

# A novel reliability aware patch selection based few shot learning for target recognition and open-set identification in ill posed SAR images

Anonymous WACV **Algorithms Track** submission

Paper ID \*\*\*\*\*

## Abstract

**001** *Earth observation with synthetic aperture radar (SAR) imagery has recently seen an extensive use of deep learning*  
**002** *for target recognition. However, SAR remains ill posed by*  
**003** *scarce labeled data, severe class imbalance and the ap-*  
**004** *pearance of open-set targets. The proposed work address*  
**005** *these challenges through a patch wise manifold learning*  
**006** *framework that integrates a residual multi-scale context-*  
**007** *ual encoder with entropy guided patch selection producing*  
**008** *structurally reliable features. On this discriminative fea-*  
**009** *tures the model optimizes instance level contrastive learn-*  
**010** *ing, prototype based clustering and an imbalance aware*  
**011** *classification loss yielding compact intraclass features and*  
**012** *interclass separation. Open-set identification is achieved*  
**013** *through a distance criterion that identifies queries with ex-*  
**014** *cessive prototype deviation enabling unknown target detec-*  
**015** *tion. Experiments on the MSTAR and SAMPLE benchmark*  
**016** *dataset demonstrate state-of-the-art performance alongside*  
**017** *substantially improved identification of previously unseen*  
**018** *targets.*

optical counterparts yet introducing challenges in interpretation [12, 18]. Speckle noise pervades SAR data and complicates segmentation and classification tasks [18]. Moreover, data heterogeneity caused by variations in incidence angle and surface structure leads to high intra-class diversity hindering the effectiveness of conventional deep learning models.

A significant challenge in SAR image analysis is the scarcity of accurately labeled datasets owing to the complexities inherent in SAR data (lack of specialized knowledge for annotation, privacy and security restrictions and the high cost of data acquisition) [1]. It results in lack of variability representation encountered in operational scenarios and subsequently limiting generalization [2]. This scarcity of labeled data has driven the adoption of semi-supervision, few shot learning and synthetic data generation strategies to supplement limited training samples [2].

Further, SAR-based machine learning pipelines are frequently grappled with the persistent problem of class imbalance presenting a nonuniform distribution of target categories [2, 15]. These imbalance means that deep learning models, when trained on such data, tend to overfit the majority classes. This develops representational bias for under-represented minority categories compromising target recognition. Conventional mitigation strategies, such as oversampling, class-rebalancing heuristics and synthetic minority generation offer only partial relief [2, 15]. They often amplify noise and escalate intra-class variability, while failing to address the heterogeneous minority samples [2]. The problem of class imbalance is further magnified when SAR recognition models must function in operational settings with limited supervision [15].

Compounding this challenge is the fundamentally open-set nature of operational SAR analysis. The datasets assume a closed set of object categories, but reality regularly encounters new, never-seen SAR classes [4, 6]. Models trained on closed-set images misclassify these unknown samples implicitly expecting that every input belongs to one of the pre-defined categories [4, 6]. This systematic

## 1. Introduction

**020** A recent technical leap in the field of modern Earth obser-  
**021** vation has emerged as Synthetic Aperture Radar (SAR) im-  
**022** ages [12]. It is a transformation extending far beyond the  
**023** optical images wherein active sensors transmit electromag-  
**024** netic pulses and record the energy reflected from the Earth's  
**025** surface. As such, these reflected backscatter signatures gen-  
**026** erate SAR imagery regardless of weather or daylight condi-  
**027** tions [12, 18]. SAR images have become indispensable for  
**028** applications ranging from environmental monitoring and  
**029** disaster assessment to defense applications, maritime safety  
**030** and urban planning [3, 12].

**031** SAR images are shaped by interactions between the  
**032** transmitted radar signal and surface geometry aided by the  
**033** illumination angle. These influences enhance SAR images  
**034** with rich structural features distinguishing them from their  
**035**

075 misalignment creates genuine risk in critical domains, such  
 076 as security monitoring or marine anomaly detection, where  
 077 failing to recognize novelty can result in threats and operational  
 078 errors [3, 12].

079 In response to these interconnected challenges, the SAR  
 080 research community has seen the emergence of advanced  
 081 deep learning techniques[18]. Among these methods contrastive  
 082 learning improves few-shot generalization under scarce labeled data while intra-class diversity pulls together  
 083 semantically similar SAR targets and pushes apart confusing  
 084 negatives in the embedding space [11]. Prototype-based  
 085 classification strengthens open-set and few-shot recognition  
 086 by forming compact class centers that support distance dis-  
 087 crimination between known and unseen targets [11]. Attention  
 088 mechanisms mitigate clutter and visual variability by  
 089 reweighting features so that the network focuses on salient  
 090 and contextual structures [17]. Multi-scale feature extrac-  
 091 tion, meanwhile, has become essential as it contains both  
 092 textural patterns and fine-grained spatial information[6, 17].

093 Despite their individual merits, these strategies have  
 094 rarely been synthesized into a unified framework that can  
 095 simultaneously confront class imbalance and deliver reliable  
 096 open-set recognition. The proposed system combines a  
 097 residual convolutional backbone capable of deep structural  
 098 feature extraction with an adaptive multi-scale context head.  
 099 It aims to enrich intermediate representations via a novel en-  
 100 tropy guided patch selection and associated heterogeneous  
 101 feature understanding. The structurally reliable patches  
 102 from all categories are emphasized while redundant major-  
 103 ity class responses are suppressed allowing minority class  
 104 features to contribute proportionally to prototype construc-  
 105 tion. The loss function cumulates contrastive, cluster-wise,  
 106 and imbalance-aware classification for organizing the fea-  
 107 ture space into compact and well separated clusters guided  
 108 by discriminative class prototypes. A dependency matrix  
 109 of the internal channels further enhance the prototype of  
 110 each class. A distance based open-set recognition mecha-  
 111 nism does not rely on auxiliary support samples and lever-  
 112 ages the learned embedding space. The framework reliably  
 113 identifies samples that do not conform to any known cat-  
 114 egory and flags them as potential unknowns. Underlining  
 115 this work is the systematic extraction of feature representa-  
 116 tions that remain robust and generalize effectively even as  
 117 SAR images remain ill posed (scarce labels, imbalance cat-  
 118 egories and open-set targets) while offering three key nov-  
 119 elties; (a) A novel reliability aware patch learning scheme  
 120 in SAR through an entropy guided patch selection to en-  
 121 sure that only discriminative, imbalance resilient and struc-  
 122 turally stable regions contribute to feature embedding, (b)  
 123 A prototype construction strategy on a dependency matrix  
 124 manifold encoding channel wise relational structures into  
 125 enhancing intra-class consistency and robustness, and (c)  
 126 A novel unified episodic learning that integrates instance-

127 level contrastive alignment, prototype-driven clustering and  
 128 an imbalance aware classification to jointly address label  
 129 scarcity and class imbalance with a distance based open-set  
 130 identification.

## 2. Related work

131 Research in target recognition of synthetic aperture radar  
 132 (SAR) imagery has grown rapidly in recent years owing  
 133 to the advances in deep neural networks. Much of this  
 134 progress, however, continues to rest on assumptions of  
 135 balanced class distributions, fully closed label spaces and  
 136 abundant training samples.

### 2.1. Scarcity of labeled SAR data

137 The deployment of deep learning in SAR imagery is con-  
 138 strained by the scarcity of labeled datasets owing to an-  
 139 notation issues. Public SAR benchmarks remain small  
 140 compared to optical-image datasets. However reviews of  
 141 SAR deep learning highlight that many early systems im-  
 142 plicitly assume abundant and balanced labeled data. Few-  
 143 shot learning has therefore become central aiming to learn  
 144 transferable representations that adapt to new classes with  
 145 only a few labeled examples [13]. Meta-learning ap-  
 146 proaches train across multiple episodes and tasks so that  
 147 the model can quickly adapt to new categories under lim-  
 148 ited supervision[9, 16]. Graph and relation based few-shot  
 149 methods, such as position aware graph neural networks,  
 150 model structural relationships between support and query  
 151 samples to improve classification in low data regimes [17].  
 152 Contrastive and prototype centered SAR frameworks lever-  
 153 age metric learning, multi-level contrastive cues and sample  
 154 mining to pull same class together while pushing different  
 155 classes apart [11, 14].

### 2.2. Class imbalance in SAR target recognition

156 The scarcity of annotations is further compounded by  
 157 class imbalance, where common target classes dominate  
 158 while rare but critical categories remain severely under-  
 159 represented [1, 8]. Constraint- and optimization-based ap-  
 160 proaches under imbalanced categories explicitly reweight  
 161 gradients or impose class-wise constraints to better pre-  
 162 serve minority-class decision boundaries. They typically  
 163 act only at the loss level and do not control which image  
 164 regions drive prototype formation [8]. Data-centric strate-  
 165 gies such as generative augmentation or entropy-based re-  
 166 sampling attempt to rebalance sample distributions by syn-  
 167 thetizing or selectively replicating minority examples while  
 168 inadvertently amplifying noise or distort the underlying fea-  
 169 tures [2]. Despite these advances, most existing methods  
 170 focus primarily on representation transfer for novel classes  
 171 and do not explicitly couple within-image patch level reli-  
 172 ability assessment for imbalance-aware prototype construc-  
 173 tion. This allows unimportant features to overfit the reliable

178 ones.

### 179 2.3. Open-Set recognition (OSR) in SAR

180 Operational SAR imaging face fundamentally open-set con-  
 181 ditions (presence of unseen targets) due to environmental  
 182 changes and anomalous events [12]. Conventional SAR  
 183 models trained under closed-set assumptions misclassify  
 184 these unseen classes into known categories. Threshold-  
 185 free open-set learning networks address this by casting OSR  
 186 as an additional class problem, thereby avoiding manually  
 187 tuned rejection thresholds [6]. Capsule network models ex-  
 188 tract pose embeddings and use divergence techniques to  
 189 separate known and unknown categories [4]. Approaches  
 190 also emphasize the importance of multi-scale feature ex-  
 191 traction to exploit both fine grained and contextual struc-  
 192 ture in SAR targets [6]. Recent work further integrates  
 193 open-set recognition with incremental learning using struc-  
 194 tural similarity based feature extraction and decision models  
 195 to progressively incorporate new targets without retraining  
 196 from scratch [7]. However, most existing methods either  
 197 rely on synthetic unknowns or heavy multitask supervision  
 198 where unreliable patches and biased prototypes can blur  
 199 the boundary between known and unknown classes. Uni-  
 200 fied method of tackling this fundamental problem posed by  
 201 unknown classes emerging at test time in limited labeled  
 202 scenario with unbalanced category distribution still lacks  
 203 enough attention.

## 204 3. Methodology

205 The proposed framework enables discriminative and open-  
 206 set aware few-shot SAR target recognition under class im-  
 207 balance.

### 208 3.1. Problem Definition

209 Let the training dataset be denoted as  $D_{base} =$   
 210  $\{(x_i, y_i)\}_{i=1}^M$ . Here,  $x_i$  denotes SAR image assigned to  
 211 a class  $y_i$  from a set of known  $n$  categories  $C_{base} =$   
 212  $\{c_1, c_2, \dots, c_n\}$ . In real SAR scenarios, the number of sam-  
 213 ples per category  $|D(c)|$  is highly imbalanced. The degree  
 214 of imbalance  $i_d$  is quantified as the ratio of the number of  
 215 samples in the category with minimum number of samples  
 216 to the category with maximum number of samples.

$$217 i_d = \frac{|D(c_{min})|}{|D(c_{max})|} \quad (1)$$

218 where,  $|D(c_{min})|$  is the number of samples of the rarest  
 219 class and  $|D(c_{max})|$  is the number of the samples of the  
 220 most-occurring class.

221 During testing, the model encounters two recognition en-  
 222 vironmental settings as explained below.

223 **1) Closed set classification:** A novel set  $D_{new}$  containing  
 224 few labeled samples and sufficiently large number of unlabeled

225 samples (representing labeled data sparsity). The la-  
 226 belled set forms the support set  $S_{new}$ , while the unlabelled  
 227 sample belonging forms the query set  $Q_{new}$ .

$$228 D_{new} = S_{new} \cup Q_{new}, \quad (2)$$

229 The set of the classes in the novel set  $D_{new}$  is denoted as  
 230  $C_{new}$ , while ensuring  $C_{base} \cap C_{new} = \emptyset$ . The objective is  
 231 to classify each query  $x \in Q_{new}$  by leveraging  $S_{new}$  and  
 232 the features of  $D_{base}$ .

233 **2) Open set recognition:** The classification of known  
 234 classes should be accompanied by the identification of sam-  
 235 ples from completely unknown categories (without any la-  
 236 bels). The label space can thus be defined as  $C_{new} \cup \{-1\}$ ,  
 237 where the label “-1” denotes unknown classes. For a given  
 238 test query sample  $x$ , the model is required to determine if it  
 239 generalize effectively to the novel target categories or reli-  
 240 ably identify unknown targets in open-set conditions.

## 241 3.2. Overview

242 As illustrated in Fig. 1, (i) meta-training is performed on  
 243 the imbalanced base set  $D_{base}$  using episodic sampling of  
 244 support and query data. Each SAR image and (a) its aug-  
 245 mented views are processed through (b) a residual encoder.  
 246 This is followed by (c) patchification of the features and (d)  
 247 an entropy-based filtering stage that retains only reliable re-  
 248 gions for feature embedding. In addition to that (e) global  
 249 features are also extracted to maintain global semantics and  
 250 are (f) aggregated with the patchified reliable feature em-  
 251 beddings. The (g) class embeddings through (h) a depen-  
 252 dence matrix manifold finally forms (i) the class prototypes.  
 253 A novel multi-level loss (instance contrastive, prototype  
 254 clustering, imbalance-aware classification) jointly optimize  
 255 (j) distance based discriminative representation learning .  
 256 During (ii) meta-testing, the trained encoder and prototype  
 257 construction pipeline are kept fixed. Query samples (from  
 258 the scarcely labelled samples) are classified via distance-  
 259 guided prototype matching, and an unknown identification  
 260 threshold enables accurate identification of unknown targets  
 261 in open-set SAR scenarios.

## 262 3.3. Meta-training

263 The meta-training stage is designed for episodic learning  
 264 that mimic few-shot classification with imbalanced and  
 265 open-set conditions. Each episode is constructed from the  
 266 base dataset  $D_{base}$  by sampling a small set of classes and  
 267 partitioning their examples into support and query subsets.  
 268 Within each episode, every support and query image is  
 269 first processed by the residual contextual encoder aided by  
 270 patch-wise decomposition, entropy-based reliability fil-  
 271 tering and multi-scale fusion of global and local descriptors.  
 272 The resulting feature vector provides the basis for learn-  
 273 ing of instance-level contrastive alignment, manifold pro-  
 274 totype regularization and imbalance aware classification. A

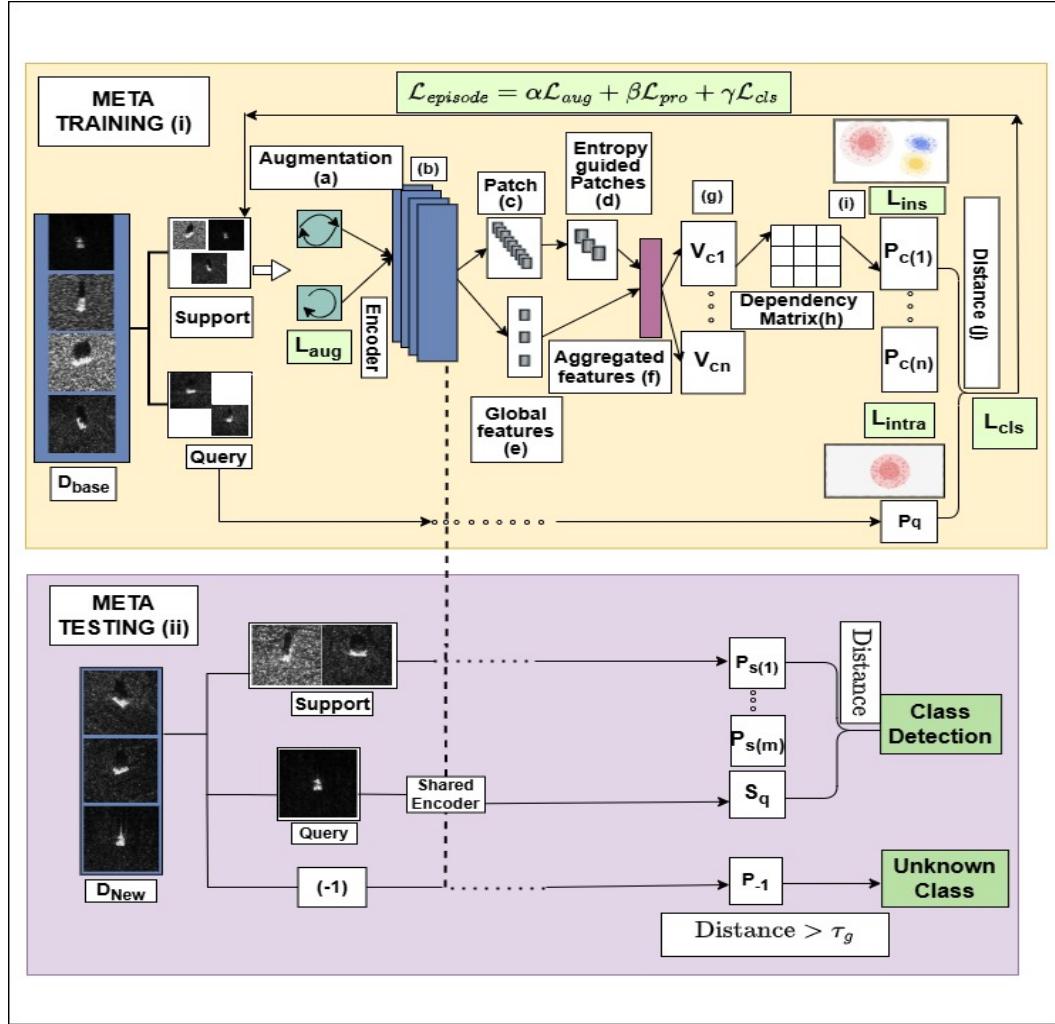

Figure 1. Overall architecture of the proposed framework.

prototype driven clustering loss then pulls query descriptors toward the prototype of their support class and pushes them away from other class prototypes. Joint optimization of these objectives guides the encoder and the prototyping module toward feature representations that are simultaneously few-shot transferable and resilient to imbalance.

### 3.3.1. Residual contextual feature encoding

The first phase of the proposed framework is the efficient feature extraction from the base set  $D_{base}$ . Each episode begins with considering a subset of the base class as a support set and query set. Given an image  $x$  from the support set, a geometric augmentation  $t(\cdot)$  produces a variant  $x' = t(x)$  that preserves semantic structure while maintaining stability under SAR imaging variations. Both  $x$  and  $x'$  are processed through a shared residual convolutional network parameterized by  $\theta$ , yielding deep spatial feature maps

$$f_\theta(x), \quad f_\theta(x') \in \mathbb{R}^{H \times W \times C}. \quad (3)$$

In an attempt to capture discriminative structures inherent to each SAR image, the feature map is partitioned into  $G \times G$  non-overlapping spatial regions.

$$f_\theta(x) = \{p_i\}_{i=1}^{G^2}, \quad (4)$$

where each  $p_i \in \mathbb{R}^{h \times w \times C}$  denotes a localized patch. These patches are converted to patch-wise vectors through a transformation function  $\phi(\cdot)$  as shown below.

$$\mathbf{z}_i = \phi(p_i) \in \mathbb{R}^d. \quad (5)$$

Each vector  $\mathbf{z}_i \in \mathbb{R}^d$  is first normalized into an activation  $a_i(k)$  using a softmax function.

$$a_i(k) = \frac{\exp(\mathbf{z}_i(k))}{\sum_{k=1}^d \exp(\mathbf{z}_i(k))}, \quad k = 1, 2, \dots, d, \quad (6)$$

where  $d$  is number of feature channels in each patch  $p_i$ . The uncertainty of patch  $p_i$  is quantified using Shannon entropy

305 as shown below.

$$306 \quad E_i = -\sum_{k=1}^d \mathbf{a}_i(k) \log \mathbf{a}_i(k), \quad (7)$$

307 A binary mask is applied to suppress unreliable patches  
308 such that

$$309 \quad m_i = \begin{cases} 1, & E_i < \tau, \\ 0, & E_i \geq \tau, \end{cases} \quad (8)$$

310 This yields the filtered descriptor.

$$311 \quad \tilde{\mathbf{z}}_i = m_i \mathbf{z}_i. \quad (9)$$

312 Only the set of low-uncertainty descriptors  $\tilde{\mathcal{Z}} = \{\tilde{\mathbf{z}}_i\}_{i=1}^{G^2}$   
313 is retained, allowing the model to focus on structurally  
314 meaningful regions. While individual patches provide  
315 localized detail, the overall target structure is captured  
316 through a global descriptor obtained by spatial average  
317 pooling as shown below.

$$318 \quad \mathbf{z}_g = \text{GlobalAvgPool}(f_\theta(x)) \in \mathbb{R}^d. \quad (10)$$

319 The multi-scale representation is then constructed by  
320 combining the global feature with the set of localized em-  
321 beddings,

$$322 \quad \mathbf{z}(x) = \psi(\mathbf{z}_g, \{\tilde{\mathbf{z}}_i\}_{i=1}^{G^2}), \quad (11)$$

323 where  $\psi(\cdot)$  denotes the fusion of global semantics and spa-  
324 tially selective features.

325 The encoder is trained using an instance-level contrastive  
326 (cross-entropy) loss using cosine similarity that aligns each  
327 sample with its augmented counterpart.

$$328 \quad \mathcal{L}_{aug} = \text{CE}(\text{cossim}(\mathbf{z}(x), \mathbf{z}(x')), Y) \quad (12)$$

329 Here,  $Y$  specifies positive pairings between each sample and  
330 its augmented view.

### 331 3.3.2. Prototype embedding

332 Following the obtaining of the aggregated descriptor  $\mathbf{z}(x)$ ,  
333 the support samples belonging to the same class are first  
334 aligned in a shared space. A transformation  $\eta(\cdot)$  is applied  
335 to generate embeddings as follows.

$$336 \quad \mathbf{v}(x) = \eta(\mathbf{z}(x)) \in \mathbb{R}^d. \quad (13)$$

337 For each class  $c_i$  in the support set, the center of that  
338 class is estimated. This yields a prototype defined by the  
339 following equation.

$$340 \quad \mathbf{v}_{c_i} = \frac{1}{|S_{c_i}|} \sum_{x \in S_{c_i}} \mathbf{v}(x). \quad (14)$$

341 where,  $S_{c_i}$  is the set of images belonging to class  $c_i$ . In-  
342 stead of relying solely on the prototype vector  $\mathbf{v}_{c_i}$ , the

343 internal relationships between feature channels are further  
344 modelled. Let  $\mathbf{v}_{c_i} = [v_{c_i,1}, v_{c_i,2}, \dots, v_{c_i,d}]$  denote the  $d$ -  
345 dimensional class prototype. All possible channel pairs  
346 ( $i, j$ ) are compared through a similarity operator  $\kappa(\cdot, \cdot)$  to  
347 generate  $m_{ij} = \kappa(v_{c_i,i}, v_{c_i,j})$  and yield a symmetric de-  
348 pendency matrix.

$$349 \quad \mathbf{M}_{c_i} = [m_{ij}] \in \mathbb{R}^{d \times d}, \quad i, j = 1, \dots, d. \quad (15)$$

350 Here,  $m_{ij}$  is the activation between channels  $i$  and  $j$ .  
351 The diagonal entries correspond to self-dependencies and  
352 are therefore less informative for discriminative purposes.  
353 Only the unique channel interactions are retained in each  
354 class prototype  $p_{c_i}$  by extracting its upper triangular por-  
355 tion.

$$356 \quad p_{c_i} = \text{Upper}(\mathbf{M}_{c_i}), \quad (16)$$

357 This process produces a compact structural reference  $p_c$   
358 for each class. During inference, a query image is processed  
359 similarly into  $\mathbf{p}_q$ , and recognition is performed by compar-  
360 ing its structural pattern with the stored prototype descrip-  
361 tors.

### 362 3.3.3. Episodic structural learning

363 During meta-training, episodic learning is employed to en-  
364 sure that the learned features generalize effectively to novel  
365 classes with only a few labeled examples. In each training  
366 episode, a support set is used to construct class prototypes  
367 in the structural space as described previously, while query  
368 samples are used to optimize loss.

369  $\mathbf{p}_q$  denote the structural descriptor of a query example  
370  $x_q$ , with  $y_q$  as its ground-truth class label. To encourage  
371 the query sample to be placed close to the prototype of its  
372 correct class  $p_{y_q}$ , a prototype-driven cluster discrimination  
373 loss is introduced to promote intra-class compactness.

$$374 \quad \mathcal{L}_{\text{intra}} = -\log \frac{\exp(-d(\mathbf{p}_q, \mathbf{p}_{y_q}))}{\sum_{c_i \in \mathcal{C}_{\text{epi}}} \exp(-d(\mathbf{p}_q, \mathbf{p}_{c_i}))}, \quad (17)$$

375 where  $d(\cdot, \cdot)$  denotes a distance metric and  $\mathcal{C}_{\text{epi}}$  represents  
376 the set of classes in the current episode.

377 At the instance level, each query is further compared  
378 with the embeddings of all support samples ensured through  
379 a loss function formulated as follows.

$$380 \quad \mathcal{L}_{\text{ins}} = \sum_{x_s \in S_{c_i}} \ell(d(\mathbf{p}_q, \mathbf{p}_{c_i}), \mathbb{I}(y_q = y_s)), \quad (18)$$

381 where  $y_s$  is the label of that particular class and  $\ell(\cdot)$  pulls  
382 together same class pairs while pushing away cross class  
383 pairs. The overall episodic optimization is expressed as the  
384 following equation.

$$385 \quad \mathcal{L}_{\text{pro}} = \eta \mathcal{L}_{\text{intra}} + \lambda \mathcal{L}_{\text{ins}}, \quad (19)$$

386 To alleviate class imbalance a classification constraint is  
 387 introduced as

$$388 \text{Logits}_{c_i} = -d(\mathbf{p}_q, \mathbf{p}_{c_i}), \quad (20)$$

389 The imbalance-aware cross-entropy (CE) loss is then for-  
 390 mulated as follows.

$$391 \mathcal{L}_{\text{cls}} = \text{CE}(\text{Logits}, y_q, w_{c_i}). \quad (21)$$

392 where,  $w_{c_i}$  is a class-frequency dependent weight that as-  
 393 signs higher importance to rare categories. Finally, the  
 394 meta-training optimization function can be expressed as fol-  
 395 lows.

$$396 \mathcal{L}_{\text{episode}} = \alpha \mathcal{L}_{\text{aug}} + \beta \mathcal{L}_{\text{pro}} + \gamma \mathcal{L}_{\text{cls}}, \quad (22)$$

397 where  $\alpha, \beta$ , and  $\gamma$  modulates the contribution of the clas-  
 398 sification constraint. This episodic objective ensures that  
 399 the structural prototype space remains well-separated across  
 400 classes, while also resilient to imbalanced sample availabil-  
 401 ity in SAR target datasets.

### 402 3.4. Meta testing and distance based open set recog- 403 nition

404 During meta-testing, the model is evaluated in an open-set  
 405 setting where two types of classes may appear; novel classes  
 406 that provide only a few labeled support samples and un-  
 407 known classes that provide no support samples at all.

408 Given a query SAR image  $q$ , its structural embedding  
 409  $\mathbf{s}(q)$  is computed using the same feature encoder and man-  
 410 ifold established during meta-training. For classes  $s_i \in$   
 411  $C_{\text{new}}$  with known prototypes of the support set  $S_{\text{new}}$  de-  
 412 noted as  $p_{s_i}$  (done as in meta-testing with frozen encoder),  
 413 the recognition of the class  $c^*$  of the query  $q$  follows a  
 414 nearest-prototype decision rule.

$$415 c^* = \arg \min_{s_i \in C_{\text{new}}} d(\mathbf{s}(q), \mathbf{p}_{s_i}), \quad (23)$$

416 The open-set scenario demands the ability to reject sam-  
 417 ples that do not belong to any known category. To achieve  
 418 this, the minimum prototype distance is compared against a  
 419 heuristically measured acceptance threshold  $\tau_{\text{global}}$

$$420 \hat{y}(q) = \begin{cases} c^*, & \text{if } \min_{s_i} d(\mathbf{s}(q), \mathbf{p}_{s_i}) \leq \tau_{\text{global}}, \\ -1, & \text{otherwise.} \end{cases}$$

421 Here, the label  $-1$  denotes a prediction into the "un-  
 422 known" class, representing targets that were not observed  
 423 during training.

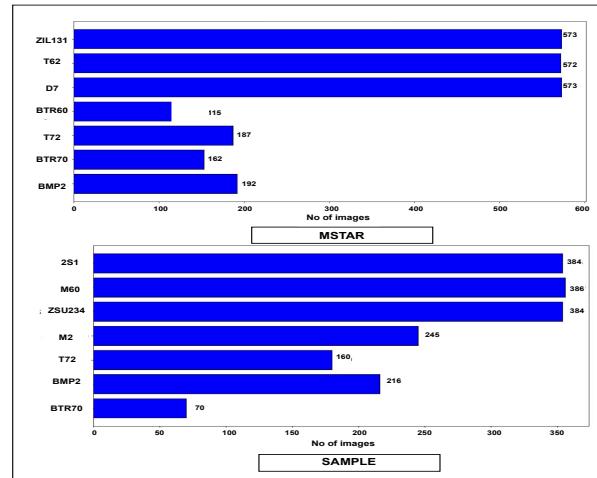

## 424 4. Results and Discussion

425 A comprehensive experimental evaluation of the proposed  
 426 framework has been made on the benchmark MSTAR and  
 427 SAMPLE datasets. At the onset an ablation study has been

conducted to validate the necessity of each architectural component. It is followed by a quantitative comparisons of the proposed work against state-of-the-art few-shot learning benchmarks. Finally, the proposed method's robustness has been validated under open-set condition.

### 428 4.1. Datasets

429 The proposed framework is evaluated using two SAR  
 430 benchmark MSTAR [10] and SAMPLE [5] datasets.  
 431 MSTAR consists of ten military vehicle categories im-  
 432 aged using X-band radar. Seven of the categories (BMP2,  
 433 BTR70, T72, BTR60, D7, T62, and ZIL131) have been  
 434 assigned as base classes, while the remaining three (2S1,  
 435 BRDM2 and ZSU234) are set as new classes. To maintain  
 436 imbalance the training samples are varied from a range of  
 437 150-520 samples per class as shown in Fig. 2. For the open  
 438 set scenario, ZSU234 has been selected as the unseen class.  
 439 The SAMPLE dataset comprises of ten types of vehicle tar-  
 440 get derived from CAD models. Seven classes has been  
 441 designated as the base set (2S1, BMP2, M2, BTR70, M60,  
 442 T72, and ZSU234). The remaining three categories (M548  
 443 M1, and M5) constitute the novel set while maintaining im-  
 444 balance in the base set as shown in Fig. 2. M1 accounts to  
 445 be the unseen class in the open set scenario.

450 Figure 2. Class imbalance in the datasets

### 451 4.2. Experimental Settings

452 The proposed model is trained under a meta-learning  
 453 paradigm using 3-way  $K$ -shot classification tasks, with  
 454  $K \in \{1, 3, 5, 7\}$ . During meta-training, each episode con-  
 455 tains 3 classes, 5 support images per class, and 15 query im-  
 456 ages in total. Novel-class support sets follow the same con-  
 457 figuration during meta-testing, whereas unknown classes

459 contribute only unlabeled query chips, reflecting realistic  
 460 open-set requirements. A class imbalance ratio of approx-  
 461 imately 1 : 5 is maintained among the base classes during  
 462 training.

463 A residual convolutional encoder with approximately  
 464 3.2M trainable parameters is used for feature extraction,  
 465 producing  $d = 256$ -dimensional patch embeddings. Patchi-  
 466 fication divides each feature map into  $G = 4$  regions. A  
 467 softmax entropy threshold, experimentally fixed at  $\tau =$   
 468 0.65, filters unreliable patches. While for open-set rejec-  
 469 tion, the global threshold  $\tau_{\text{global}} = \mu_d + 3\sigma_d$  is computed  
 470 using the mean  $\mu_d$  and standard deviation  $\sigma_d$  of the support  
 471 prototype distance distribution. Training is performed using  
 472 Adam optimizer with learning rate  $1 \times 10^{-4}$  and weight de-  
 473 cay  $5 \times 10^{-4}$ . Each model is trained for 1000 episodes with  
 474 batch size 1 episode. This experimental configuration repli-  
 475 cates real SAR target recognition where data is imbalanced,  
 476 annotated samples are scarce, and unseen targets must be  
 477 reliably rejected.

### 478 4.3. Ablation Studies

479 To assess the independent contribution of each module  
 480 within the proposed framework, ablation experiments un-  
 481 der 3-way 1-shot and 3-way 5-shot configurations have been  
 482 conducted. The results, summarized in Table 1, demon-  
 483 strate that the absence of any core module leads to a mea-  
 484 surable decline in classification accuracy.

Table 1. Ablation study performance under few-shot settings.

Absent module	3-way 1-shot (%)		3-way 5-shot (%)	
	MSTAR	SAMPLE	MSTAR	SAMPLE
Patchification	81.53	80.42	86.28	84.50
Entropy Filtering	84.39	82.56	88.25	86.54
Cluster Consistency Loss	86.61	84.59	90.16	88.67
Dependency Matrix	87.25	85.32	91.08	89.92
<b>Proposed</b>	<b>91.12</b>	<b>90.58</b>	<b>95.92</b>	<b>94.26</b>

485 The improved performance observed in the combined  
 486 framework confirms the the functional necessity of each  
 487 components for generating the discriminative feature rep-  
 488 resentations necessary for the classification.

489 To provide a qualitative assessment of the learned rep-  
 490 resentation space, t-SNE visualizations are generated for  
 491 the structural embeddings under balanced, imbalanced, and  
 492 open-set conditions. As shown in Fig. 3, the proposed work  
 493 forms compact and well-separated clusters for known tar-  
 494 get categories strongly even for the imbalanced training set.  
 495 For the unknown target, a separate sample cluster forms,  
 496 however, with more outliers as compared to the previous  
 497 settings. This confirms that the model effectively enhances  
 498 both intra-class compactness and inter-class separability,  
 499 supporting reliable open-set rejection.

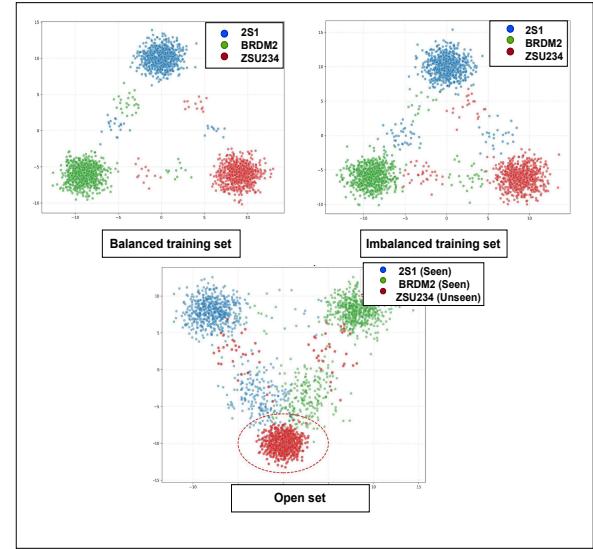

Figure 3. t-SNE visualization of structural embeddings learned under balanced, imbalanced, and open-set scenarios.

### 500 4.4. Comparison with state-of-the-art approaches

501 The proposed work has been compared with five state-of-  
 502 the-art few-shot classification approaches. In each of the  
 503 work imbalance has been introduced in the training with an  
 504 imbalance degree of 1:5. The classification accuracy on the  
 505 has been computed as the following equation

$$\text{Accuracy} = \frac{\text{Number of correct predictions}}{\text{Total number of query samples}} \times 100\%. \quad (24)$$

506 The quantitative classification accuracies have been pre-  
 507 sented in Table 2.

Table 2. Benchmark comparison on imbalanced MSTAR and SAMPLE few-shot classification.

Method	Acc. (%) for 3-Way K-Shot Classification							
	MSTAR				SAMPLE			
	K=1	K=3	K=5	K=7	K=1	K=3	K=5	K=7
ConvT[13]	77.76	79.78	81.05	82.43	76.12	80.82	82.15	82.56
Meta-FSCIL[9]	81.09	83.34	83.82	84.54	78.05	81.15	82.83	86.79
Position-aware [17]	81.76	86.15	87.56	89.87	79.70	83.07	85.78	89.50
MHD-ProtoNet[14]	88.67	90.56	91.87	92.06	88.09	88.53	90.59	90.72
MCL-DMM[11]	90.79	92.17	93.05	93.97	89.73	91.55	91.82	92.75
<b>Proposed</b>	<b>91.12</b>	<b>94.84</b>	<b>95.92</b>	<b>96.24</b>	<b>90.58</b>	<b>92.95</b>	<b>94.26</b>	<b>94.89</b>

510 The results in Table 2 show that methods based on con-  
 511 ventional convolutional backbones (ConvT [13]) struggle  
 512 to maintain high recognition accuracy when faced with  
 513 both data scarcity and class-frequency skew. Their per-  
 514 formance remains consistently lower by  $\approx 12 - 15\%$  across all

shot settings and on both datasets as compared to the proposed method. The proposed method surpasses the generic meta-learning and graph-based methods, Meta-FSCIL[9] and Position-aware [17] by  $\approx 6 - 10\%$ . Prototype based baselines such as MHD-ProtoNet[14] and MCL-DMM[11] achieve stronger results, yet they still exhibit substantially lower recognition accuracy of ( $\approx 2 - 4\%$ ) with the proposed method when introduced to imbalanced and limited support samples. Under such imbalanced scenarios, the compared methods suffer prototype deformation since the structural information becomes strongly biased by unimportant responses mainly in the imbalanced class. In contrast, the proposed method introduces an entropy-based patch filtering that discards uncertain local responses before prototype construction. Consequently, it achieves the highest accuracy in every configuration across both datasets. The proposed work achieves an accuracy of 91% for MSTAR and 90.58% for SAMPLE in the 1-shot case, while consistently maintaining superior accuracy for  $K = 3, 5$ , and 7.

These results demonstrate that combining discriminative structural embedding with reliability assessment enables the proposed work to extract more distinctive features than existing methods. This makes it significantly more resilient to class imbalance and scarce occurrences.

#### 4.5. Open-Set Recognition Evaluation

The proposed framework's capability was next assessed for open-set recognition (OSR), which measure its ability to accurately classify known targets while simultaneously identifying unknown, unobserved targets encountered during testing while maintaining the imbalance ratio. In each of the dataset, one class has been made unknown. The known class as well as unknown class accuracy is measured in a 3 way 3 shot setting. Table 3 presents the OSR results on the MSTAR and SAMPLE dataset.

Table 3. Open-set recognition performance comparison on MSTAR and SAMPLE.

Method	Known Class Acc. (%)		Unknown Class Acc. (%)	
	MSTAR	SAMPLE	MSTAR	SAMPLE
Incremental[7]	90.32	88.76	73.71	69.93
Threshold-free[6]	89.10	87.45	70.60	68.97
Capsule + KLD[4]	88.87	89.12	71.89	69.28
Proposed	<b>91.42</b>	<b>90.01</b>	<b>79.81</b>	<b>74.56</b>

The state-of-the-art OSR methods exhibit comparatively weaker identification capability due to their feature distributions placing both discriminative and unimportant features in the embedding space. The proposed work leverages its entropy-based filtering to discard unreliable or clutter regions that typically confuse similarity metrics. The dependence matrix prototype further captures channel wise relations unique to each known target category. As a re-

sult, unknown class embeddings naturally remain distant from all known prototypes enabling confident rejection. Consequently, the proposed method delivers reliable open-set behavior achieving 79.81% unknown class accuracy on MSTAR and 74.56% on SAMPLE. This demonstrates an improvement of 6 – 11% over the state-of-art OSR approaches. It further demonstrates superior known class classification accuracy by surpassing the state-of-the art OSR approaches by  $\approx 2 - 3\%$ . However, the known class accuracy is seen to decrease by 3% in MSTAR and 2% in SAMPLE in the proposed method with the introduction of open-set targets as compared to all known targets (Table 2).

#### 5. Conclusion

The proposed method presents a novel few-shot SAR target recognition and open-set identification designed to operate effectively under class imbalance. By integrating residual contextual encoding, entropy-guided patch selection and dependence aware prototype learning, the proposed method generates discriminative and reliable representations even with limited imbalanced labeled samples. Extensive experiments conducted on the MSTAR and SAMPLE datasets demonstrate the proposed method's superiority in few-shot classification while maintaining substantially high rejection rate for open-set targets as compared to state-of-the-art approaches. Notably, the proposed approach preserves prototype integrity for rare target categories through the integration of entropy based reliable patch learning while also considering the internal dependence of each class's prototype channels. In future work, it is intended to extend the study to support multi-modal learning and to explore self-supervised pretraining for enhancing resilience against domain shifts.
